Filter Design Basics. A common DSP task is to design a frequency-selective lter to approximate either a desired impulse response or desired frequency response within certain tolerances. The typical procedure is:  
1.Specify the desired properties of the lter 2.Determine the coe cients of linear constant-coe cient causal di erence equation that meets the speci cations 3.Implement the discrete-time system in a particular realization structure.

A FIR filter is used to implement almost any type of digital frequency response. Usually these filters are designed with a multiplier, adders and a series of delays to create the output of the filter. The following figure shows the basic FIR filter diagram with N length. The result of delays operates on input samples.
